Corrosão e os Anodos

Qualquer embarcação atracada ou navegando em água doce, salgada ou salobra, está sujeita à corrosão e seus efeitos geram consequências graves ocasionandoelevados custos para seus proprietários.

Os metais quando imersos em um eletrólito (água do mar por exemplo) têm diferentes potenciais eletroquímicos quando em contato um com o outro, e formam uma célula galvânica. O metal com menor potencial na célula galvânica (menos nobre) será então corroído e o com maior potencial (mais nobre) será protegido, tomemos como exemplo prático o hélice de bronze e o eixo de aço inox mergulhados na água do mar, como o bronze do hélice é menos nobre, ele será corroído e o eixo de aço inox estará protegido.

Caso cogite proteger ambos os metais (tanto o bronze do hélice como o eixo de inox), é preciso conectar um terceiro metal que é mais ativo (menos nobre) do que os dois primeiros. O metal mais ativo (zinco por exemplo) torna-se o anodo para os outros e é sacrificado pela corrosão, protegendo o catodo (o hélice e o eixo de inox), então temos o anodo de sacrifício. Para uso prático, recorre-se a série galvânica de materiais metálicos em relação a água do mar, que constituem a ordenação dos metais segundo seu comportamento neste meio e que mostramos a seguir na figura 1:

A primeira propriedade à ser considerada é o seu potencial elétrico:

Magnésio gera -1,6V

Liga de alumínio/índio gera -1,1V Zinco gera -1,05V Para que se obtenha maior proteção, é necessário que se consiga a maior diferença de tensão praticávelentre o anodo de sacrifício e o metal à ser protegido.

Por exemplo:

O zinco é usado para proteger o hélice de bronze, temos o zinco = -1,05V e o bronze = -0,3V , então temos -1,05 – (-0,3) = -0,75V.

(- 1,6V)	Magnésio
(- 1,5V)	
(- 1,4V)	
(- 1,3V)	
(- 1,2V)	
(- 1,1V)	Liga de Alumínio/ Índio
(- 1,05V)	Liga de Zinco
(- 0,9V)	Alumínio
(- 0,8V)	
(- 0,7V)	Cádmio
(- 0,6V)	Aço de Baixo Carbono
(- 0,5V)	Aço inox 304 e 316 (ativo)
(- 0,4V)	Bronze alumínio
(- 0,3V)	Bronze naval
(- 0,2V)	Latão
(- 0,1V)	
(0,0V)	Aço inox 304 e 316 (passivo)
(+0,1V)	Prata
(+0,2V)	Ouro
(+0,3V)	Grafite

Usando a liga alumínio/índio para proteger o bronze, temos a liga alumínio/índio = -1,10V e o bronze = -0,3V, então temos -1,10 – (-0,3) = -0,8V.
Pelo mostrado acima a liga alumínio/índio oferece maior proteção para o hélice.

A segunda propriedade mais importante é a capacidade de corrente do material do anodo.

O anodo gera uma diferença de voltagem e este conduz uma corrente entre o anodo e o metal protegido através da água. Então quanto maior capacidade, mais tempo vai continuar protegendo. Aliás, para um anodo em particular, a taxa do fluxo de corrente depende da área de superfície do anodo e a longevidade depende da massa(tamanho) do anodo. Para o mesmo tamanho do anodo, as capacidades relativas em dias são:

Zinco = 100
Magnésio = 30.
Alumínio = 130/150 (depende do fabricante).

Resumindo, se você utilizar um anodo de magnésio no lugar do anodo de zinco, ele só iria durar apenas 30 dias. Caso utilize o anodo de alumínio ele iria durar entre 130 e 150 dias. A terceira propriedade é a qualidade da liga do anodo. Um cuidado que você deve ter é com a qualidade dos metais utilizados, não é qualquer zinco ou alumínio que vai funcionar. Existem anodos de qualidade questionável. É importante assegurar-se de que os anodos adquiridos são fabricados dentro das normas existentes.
As normas que a **ZIGMO** utiliza são:

Zinco: ABNT-NBR 9358 (BRASIL) / MIL-A-18001K (USA);

Alumínio: ABNT-NBR 10387 (BRASIL) / MIL-A-24779(SH) (USA);

Magnésio: ABNT-NBR 16460 (BRASIL) / MIL-A-21412(SH)(USA).

Selecione o anodo correto para as águas que sua embarcação navega

Nem todos os anodos são adequados para qualquer ambiente aquático, por exemplo,a superfície de um anodo de zinco quando fica em água doce ou salobra durante algum tempo, torna-se coberta por uma crosta branca formada por óxidos que efetivamente impede o anodo de continuar funcionando, mesmo quando retorna para água salgada.

Já o anodo de alumínio vai continuar operando de forma eficaz em estuários de rios e em outras áreas de água salobra indefinidamente. As conseqüências dessa passividade do anodo é que o próximo item mais anódico dentro da embarcação vai começar a corroer.

O proprietário da embarcação deve saber qual o material do anodo adequado ao ambiente onde navega.

Os anodos devem ser selecionados com base na tabela mostrada à seguir:

LIGA	ÁGUA DOCE	ÁGUA SALOBRA	ÁGUA SALGADA
Zinco	∅	∅	✓
Alumínio	✓	✓	✓
Magnésio	✓	∅	∅

Algumas embarcações movimentam-se durante algum tempo entre água doce e água salgada, outras estão atracadas dentro de marinas e atrás de barreiras de marés onde a água é susceptível de ser salobra ou mesmo praticamente doce. Os proprietários devem estar conscientes dos efeitos que isso pode ter sobre sua embarcação e utilizar anodo correto para evitar a corrosão.

Por isso é muito importante verificar os anodos após quaisquer viagens em água doce ou água salobra, se necessário, limpar ou trocar o anodo.

Os anodos de magnésio são mais eficientes que os de zinco e os de alumínio na água doce, uma vez que a água doce é muito menos condutora que a água salgada, os anodos de magnésio são a melhor escolha, porque eles são mais ativos (menos nobre) que os de zinco e os de alumínio, protegendo assim, sua embarcação de maneira mais eficaz.CUIDADO, não use anodos de magnésio em qualquer aplicação que não seja água doce, porque eles vão corroer rapidamente, expondo sua embarcação e o seu motor a possíveis danos.

Anodo de alumínio fornece maior proteção e dura mais tempo que o anodo de zinco. Ele continuará a trabalhar em água doce e é seguro para uso em água salgada e água salobra, ou seja, o anodo de alumínio é seguro em todas as aplicações.

Rabetas e motores de popa requerem um pouco mais de cuidado. Os anodos de sacrifício têm uma tarefa mais difícil, uma vez que tem que proteger o que é uma estrutura de alumínio muito ativa. Inicialmente estes anodos para estas unidades eram de zinco, mas em resposta a problemas de corrosão, Mercury e Johnson/Evinrude/OMC, começaram a vender anodos de alumínio no início dos anos 90. Outros fabricantes passaram também a utilizar os anodos de alumínio. O pequeno aumento de voltagem de proteção ajuda a garantir que a sua rabeta ou seu motor fiquem protegidos.

Uma questão que surge é a dúvida de como um anodo de alumínio pode proteger a rabeta e o motor que são fabricados em alumínio. A proteção se dá porque os anodos de alumínio são uma liga de alumínio, zinco e índio. É como comparar aço comum e aço inoxidável, eles tem propriedades muito diferentes. O zinco e o índio tornam o metal mais ativo e impedem a formação da película de óxidos no alumínio, fazendo que o anodo continue a funcionar normalmente.

Então diante do exposto acima, podemos enumerar algumas vantagens de se usar os anodos de alumínio, tais como:

1. Performance melhor que o tradicional anodo de zinco para água salgada.
2. Dura até 50% mais do que o anodo de zinco tradicional.
3. Pesa quase a metade do que o anodo de zinco tradicional.
4. Atende tanto as normas da ABNT(Brasil) e da U S MILITARY SPECIFICATION(USA).
5. É o único anodo eficaz em todos tipos de água.
6. Resulta em considerável economia de custos em comparação com os anodos de zinco tradicionais.
7. A MAIS IMPORTANTE DE TODAS, CONTÉM 0% DE CÁDMIO, METAL ALTAMENTE TÓXICO ENCONTRADO NOS TRADICIONAIS ANODOS DE ZINCO, TORNANDO-SE AMIGO DO MEIO AMBIENTE.

Assim o anodo de alumínio possui características técnicas, econômicas e ambientais espetaculares que estamos colocando à disposição do mercado consumidor para o adequado, eficiente e econômico combate a corrosão.

Ligas para fabricação de anodos de sacrifício

A **ZIGMO** fabrica três tipos de ligas para os três ambientes de água, ou seja, água doce, água salobra e água salgada.

Cada liga utilizada é garantia de ser fabricada na mais recente especificação da ASSOCIAÇÃO BRASILEIRA DE NORMAS TÉCNICAS-ABNT e da US MILITARY ALLOY SPECICICATION (USA), a composição química é analisada regularmente em laboratório para garantir a qualidade da mesma, pois pequenas quantidades de outros elementos atuam como impurezas fazendo com que o anodo passive e deixe de proteger contra a corrosão, causando sérios danos e elevados custos para o proprietário. Então, nem todos os anodos são produzidos da mesma maneira, tenha certeza de adquirir um genuíno anodo fabricado pela **ZIGMO**.

LIGAS DE ZINCO

Normas: ABNT- NBR 9358 (BRASIL) / US MIL-A-18001-K (USA)

Cobre	0,005% máximo
Ferro	0,005% máximo
Chumbo	0,006% máximo
Cádmio	0,025% até 0,07%
Alumínio	0,1% até 0,5%
Zinco	restante

Os metais aditivos alumínio e cádmio, são usados para produzir um grão mais fino na estrutura do metal fundido, evitando também a polarização anódica causada por formações contínuas, com isso conseguimos uma eficiência prática na capacidade de intensidade de corrente mais elevada, além de neutralizar a ação do ferro residual existente no zinco SHG (Special High Grade) utilizado pela **ZIGMO**.

LIGAS DE ALUMÍNIO

Normas: ABNT-NBR 10387 (BRASIL) / US MIL-A-24779(SH) (USA)

Cobre	0,004% máximo
Ferro	0,09% máximo
Índio	0,014% até 0,02%
Silício	0,08% até 0,2%
Zinco	4,0% até 6,0%
Alumínio	restante

Os metais aditivos índio e zinco devem inibir a formação da película de óxido, que é um fator indispensável ao uso do alumínio marcadamente menos nobre que o magnésio e o zinco. Esta película é uma qualidade desejável e vitalmente importante para a manufatura de artigos de alumínio, mas ela limita o uso do metal como anodo. Ao usar o índio e o zinco conseguimos uma eficiência na prática na capacidade de corrente de até 95%.

LIGAS DE MAGNÉSIO

Norma: ABNT-NBR 16460 (BRASIL) / US MIL-A-21412(SH) (USA)

Cobre	0,10% máximo	Zinco	2,0% até 4,0%
Ferro	0,003% máximo	Alumínio	5,0% até 7,0%
Níquel	0,03% máximo	Manganês	0,15% até 0,55%
Silício	0,30% máximo	Magnésio	restante

Al	*ZMASAl*	*304,00*	*1,200*	***mm*** *in.*	***50,8*** *2”*	***203*** *8”*

Anodos suspensos em Liga de Alumínio com cabo de aço galvanizado revestido em vinil, 5 metros de comprimento e terminal para ligação no aterramento da embarcação.

O anodo suspenso é muito comum para a proteção em docas e marinas, eles podem estender a vida útil de seus anodos de eixo e ponta de eixo, quando conectados ao sistema de aterramento da embarcação e colocados na água.

São recomendados para proteção contra a corrosão em todos os tipos de embarcações.

TERMINAL

	Ref.	R$	Kg
Pb	*ZMTBE*	*35,00*	*0,315*
Conjunto de terminais de chumbo positivo e negativo com parafuso do poste com encaixe na peça			

	Ref.	R$	Kg
Pb	*ZMTBF*	*35,00*	*0,315*
Conjunto de terminais de chumbo positivo e negativo com parafuso do poste fundido na peça			

O terminal é um tipo de dispositivo de fixação. Seu objetivo é fornecer uma conexão sólida entre as duas extremidades da fiação entre si ou em uma fonte de energia.
